# 1 Introduction

The aim of the report is to explain the process and results of four experiments named as string concatenation, string builder concatenation, insertion sort and merge sort in 1 second. The report also covers the description of why string builder is faster than string during concatenation. The table shows result time in milliseconds<sup>1</sup>. All the results were taken after running the experiment number of times. The result tables also shows the average result.

## 2 String Concatenation

### 2.1 Aim

The *aim* of this experiment is to find out how many short strings(*string with 1 character*) and long strings (*string with 80 characters*) can be added to a string in 1 second using + operator.

### 2.2 Procedure

- 1) Firstly, one empty string has been created and initialised.
- 2) Then, one variable (*named as start*) has been created which return the time in milliseconds. This variable used java library class method named `System.currentTimeMillis()` for returning time.
- 3) Furthermore, a while loop has been established which runs until current milliseconds - variable (*start*) is less than 1000 milliseconds. Inside this loop, short string or long string (*depends on experiment*) was added using + operator.
- 4) After this loop, one more variable (*named as end*) has been declared which also return time by using `System.currentTimeMillis()` methods. This variable helped to find the runtime. For instance, when the while loop ends, the difference between this variable (*end*) and variable (*start*) is the runtime.
- 5) During the short string case, the length of the string and number of concatenation was same. However, during the long string I divided the string length by 80 in order to find the number of concatenation.

---

<sup>1</sup> 1 second = 1000 milliseconds

## 2.3 Results

String with 1 character

| S. No          | Time<br>(Milliseconds) | Concatenations | Length       |
|----------------|------------------------|----------------|--------------|
| 1              | 1000                   | 20676          | 20676        |
| 2              | 1000                   | 20780          | 20780        |
| 3              | 1000                   | 20767          | 20767        |
| 4              | 1000                   | 20783          | 20783        |
| 5              | 1000                   | 20807          | 20807        |
| 6              | 1000                   | 20695          | 20695        |
| 7              | 1000                   | 20774          | 20774        |
| 8              | 1000                   | 20750          | 20750        |
| 9              | 1000                   | 20677          | 20677        |
| 10             | 1000                   | 20727          | 20727        |
| <u>Average</u> | <u>1000</u>            | <u>20743</u>   | <u>20743</u> |

String with 80 characters

| S.No           | Time<br>(Milliseconds) | Concatenations | Length        |
|----------------|------------------------|----------------|---------------|

| 2              | 1000                   | 1731           | 138480        |
| 3              | 1000                   | 1740           | 139200        |
| 4              | 1000                   | 1720           | 137600        |
| 5              | 1000                   | 1733           | 138640        |
| 6              | 1000                   | 1730           | 138400        |
| 7              | 1000                   | 1730           | 138400        |
| 8              | 1000                   | 1727           | 138160        |
| 9              | 1000                   | 1720           | 137600        |
| 10             | 1000                   | 1724           | 137920        |
| <u>Average</u> | <u>1000</u>            | <u>1728</u>    | <u>138304</u> |

### 3 StringBuilder Appending

#### 3.1 Aim

The *aim* of this experiment is to find out how many short strings(*string with 1 character*) and long strings (*string with 80 characters*) can be appended to the string builder in 1 second using append method.

#### 3.2 Procedure

The approach is basically the same as string concatenation experiment. The only difference is to add the new string in a string builder using append method and use toString() method at last.

- 1) Firstly, one string builder has been created.
- 2) Then, one variable (*named as start*) has been created which return the time in milliseconds. This variable used java library class method named System.currentTimeMillis() for returning time.
- 3) Furthermore, a while loop has been established which runs until current milliseconds - variable (*start*) is less than 1000. Inside this loop, short string or long string (*depends on experiment*) was added using + operator.
- 4) After this loop, one more variable (*named as end*) has been declared which also return time by using System.currentTimeMillis() methods. This variable helped to find the runtime. For instance, when the while loop ends, the difference between this variable (*end*) and variable (*start*) is the runtime.
- 5) Then, I converted the string builder to string using toString() method and save the time in a variable
- 6) Again, I run the while loop, but this time it will run until it is smaller than 1000 milliseconds - toString time. Inside this loop, I again added short or long string (*depends on experiment*) in a new string builder.
- 7) During the short string case, the length of string and number of concatenation is same. However, during long string I divided the string length by 80 in order to find the number of concatenation.
- 8) The *problem* during the long string case was that it usually takes more time than 1000 milliseconds due to the fact that adding long string takes more time than adding short ones. For instance, if adding long string takes more than 1 milliseconds and the time is 999. The while loop is still true and add the long string but then the runtime become bigger than 1000.

### 3.3 Results

StringBuilder with 1 character

| S.No           | Time<br>(Milliseconds) | Concatenations  | Length          |

## 4 Insertion Sort

### 4.1 Aim

The *aim* of this experiment is to find out how many integers and characters can be sorted in 1 second using insertion sort algorithm.

### 4.2 Procedure

- 1) Firstly, an array of length 1000 has been created which contains random numbers twice then the length of it. For instance, if the array size is 1000 and it contains random number 2 times array length (*from 0 - 1999*). The strategy is same even if it is string array because I created my own string which contains all upper and lower case letters.
- 2) Then I started the while loop with a condition that if runtime is equal to or greater than 1000 then stop otherwise run continuously.
- 3) Inside the while loop, I initialised the two variables, one above and one below the insertion algorithm process in order to get the runtime for sorting the array of different lengths.
- 4) Furthermore, inside the while loop I added some additional if and else if statements in order to get the result as accurate as possible. Each time, I am increasing the size of array if runtime is less than 1000 milliseconds or vice versa.
- 5) The purpose of these additional statements is to increase or decrease the size of array at different stages. For instance, if runtime is more than 1000 milliseconds then one of this statement will run and decrease the size of array by 1 and initialised the runtime to 0 so that while loop will not stop. Other statements are for general purpose, such as break the loop if runtime is 999 or 1000 or 1001 to get approximate result and increase the size slowly if runtime is near to 1000 milliseconds.
- 6) Three additional methods have been created. Two for generating a new array with random number and random characters and one for calculating the average time and length. The average method I created for myself to find the approximate time for sorting integers and characters arrays of different lengths. This method is extra work and I am only running it when runtime is between 950 and 1000 milliseconds because there is no need to find the average from beginning of the runtime.
- 7) This approach takes bit more time as it will only stop if one the statement inside the while statement will be true.
- 8) The advantage of this approach is to get accurate result on different computers. For instance, if I only run the while loop until runtime is smaller than 1000 milliseconds, I will not get the accurate result. I saw that java compiler always improve my code. For instance, if 100000 integers is sorted in 300 milliseconds, next time the array which is bigger in length can be sorted in less than 300 milliseconds and then even more less. Due to these facts, I added some additional statements as I mentioned above.

### 4.3 Results

Integer Insertion Sort

| S.No           | Time<br>(Milliseconds) | Array Length |

## 5 Merge Sort

### 5.1 Aim

The *aim* of this experiment is to find out how many integers and characters can be sorted in 1 second using merge sort algorithm.

### 5.2 Procedure

The approach is basically the same as insertion sort. The only difference is to execute merge sort algorithm rather insertion sort.

- 1) Firstly, an array of length 1000 has been created which contains random numbers twice then the length of it. For instance, if the array size is 1000 and it contains random number 2 times array length (*from 0 - 1999*). The strategy is same even if it is string array because I created my own string which contains all upper and lower case letters.
- 2) Then I started the while loop with a condition that if runtime is equal to or greater than 1000 then stop otherwise run continuously.
- 3) Inside the while loop, I initialised the two variables, one above and one below the insertion algorithm process in order to get the runtime for sorting the array of different lengths.
- 4) Furthermore, inside the while loop I added some additional if and else if statements in order to get the result as accurate as possible. Each time, I am increasing the size of array if runtime is less than 1000 milliseconds or vice versa.
- 5) The purpose of these additional statements is to increase or decrease the size of array at different stages. For instance, if runtime is more than 1000 milliseconds then one of this statement will run and decrease the size of array by 1 and initialised the runtime to 0 so that while loop will not stop. Other statements are for general purpose, such as break the loop if runtime is 999 or 1000 or 1001 to get approximate result and increase the size slowly if runtime is near to 1000 milliseconds.
- 6) Three additional methods have been created. Two for generating a new array with random number and random characters and one for calculating the average time and length. The average method I created for myself to find the approximate time for sorting integers and characters arrays of different lengths. This method is extra work and I am only running it when runtime is between 950 and 1000 milliseconds because there is no need to find the average from beginning of the runtime.
- 7) This approach takes bit more time as it will only stop if one the statement inside the while statement will be true.
- 8) The advantage of this approach is to get accurate result on different computers. For instance, if I only run the while loop until runtime is smaller than 1000 milliseconds, I will not get the accurate result. I saw that java compiler always improve my code. For instance, if 100000 integers is sorted in 300 milliseconds, next time the array which is bigger in length can be sorted in less than 300 milliseconds and then even more less. Due to these facts, I added some additional statements as I mentioned above.

### 5.3 Results

Integer Merge Sort

## 6 Why StringBuilder is Faster?

Before explaining why string builder is faster than string concatenation using the + operator, I want to tell that string concatenation also use string builder to add another string. For instance,

```
String str1 = "";  
String str2 = "Java";  
str1 = str1 + str2;  
str = "Java";
```

This actually happens like this:

```
StringBuilder sb = new StringBuilder();  
str = sb.append(str2).toString();
```

The reason why string builder is faster is that string concatenation using + operator makes a copy during each concatenation which requires memory to save and time to make that copy. Whereas, string buider adds the new string at the end position and only make copy in some cases such as during resize or if inserting element in the middle. In the experiment, I am only adding the string which means string builder only saves copy when the data becomes to big. That is why there is a big difference in the result.
